

ABSTRACT

A remote control providing the means for making adjustments to a plurality of electronic display screens. The remote control provides the means to control a selected group or groups from the array of electronic displays or of the entire array of multiple electronic display screens. The commands being sent would include but are not limited to brightness up and down, contrast up and down, input source, color intensity, aspect ratio, 'on/off' features and other commands or adjustments applicable to an array of multiple electronic displays. The adjustments can be made simultaneously or in a desired sequence. The remote control transmits information via infra-red, radio frequency or other wireless means to a remote sensor with a microprocessor located within the electronic display or to a central microprocessor that serves to further the signal to each electronic display.
